1. I made 5 functions.

- add_numbers for addition.
- subtract_numbers for subtraction.
- multiply_numbers for multiplication.
- divide_numbers for division.
- main manages the user inputs and program execution.

2. The math functions used num1 and num2 as empty placeholders waiting for numbers to be given by the user but the main() function did not use any parameters.

3. The float variables num1 and num2 (which store the numbers entered by the user) were passed as arguments when calling the selected function inside the if-elif blocks.

4. The program caught the final answer and stored it in a named result. It displayed that final answer on the screen for the user to see.

5. It keeps the code neat instead of messy. It is faster to find and fix mistakes. I can reuse the same math blocks later without rewriting them.
